Provision an EKS Cluster (AWS)

★ Add bookmark

AWS's Elastic Kubernetes Service (EKS) is a managed service that lets you deploy, manage, and scale containerized applications on Kubernetes.

In this tutorial, you will deploy an EKS cluster using Terraform. Then, you will configure kubectl using Terraform output and verify that your cluster is ready to use.

Warning

AWS EKS clusters cost \$0.10 per hour, so you may incur charges by running this tutorial. The cost should be a few dollars at most, but be sure to delete your infrastructure promptly to avoid additional charges. We are not responsible for any charges you may incur.

Why deploy with Terraform?

While you could use the built-in AWS provisioning processes (UI, CLI, CloudFormation) for EKS clusters, Terraform provides you with several benefits:

- Unified Workflow If you already use Terraform to deploy AWS infrastructure, you can use the same workflow to deploy both EKS clusters and applications into those clusters.
- Full Lifecycle Management Terraform creates, updates, and deletes tracked resources without requiring you to inspect an API to identify those resources.
- Graph of Relationships Terraform determines and observes dependencies between resources. For example, if an AWS Kubernetes cluster needs a specific VPC and subnet configurations, Terraform will not attempt to create the cluster if it fails to provision the VPC and subnet first.

Prerequisites

The tutorial assumes some basic familiarity with Kubernetes and kubectl but does not assume any pre-existing deployment.

You can complete this tutorial using the same workflow with either Terraform OSS or Terraform Cloud. Terraform Cloud is a platform that you can use to manage and execute your Terraform projects. It includes features like remote state and execution, structured plan output, workspace resource summaries, and more.

Select the **Terraform OSS** tab to complete this tutorial using Terraform OSS.

This tutorial assumes that you are familiar with the Terraform and Terraform Cloud workflows. If you are new to Terraform, complete the <u>Get Started collection</u> first. If you are new to Terraform Cloud, complete the <u>Terraform Cl oud Get Started tutorials</u> first.

For this tutorial, you will need:

- Terraform v1.3+ installed locally.
- a <u>Terraform Cloud account</u> and organization.
- Terraform Cloud locally authenticated.
- a Terraform Cloud variable set configured with your AWS credentials.
- an AWS account
- the AWS CLI v2.7.0/v1.24.0 or newer, installed and configured
- AWS IAM Authenticator
- kubectl v1.24.0 or newer

Set up and initialize your Terraform workspace

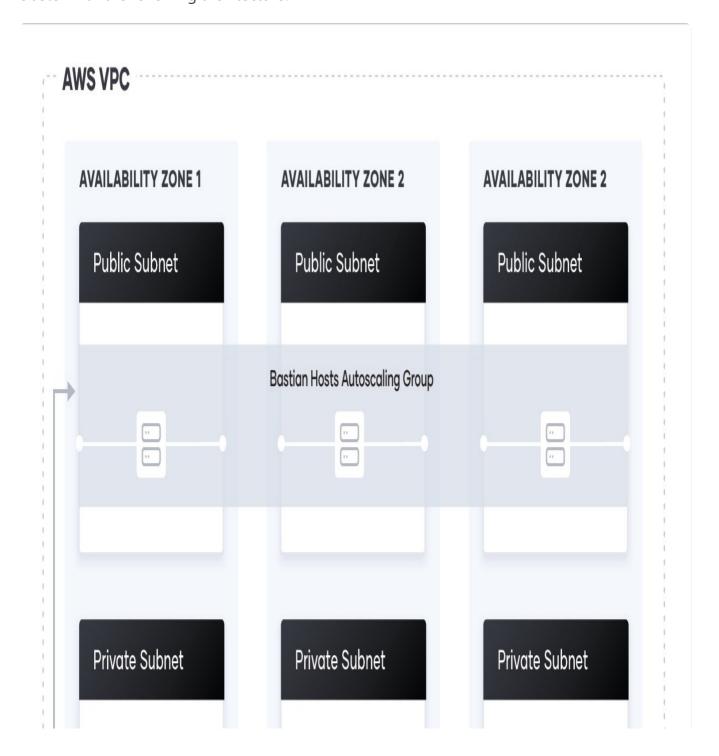

In your terminal, clone the example repository for this tutorial.

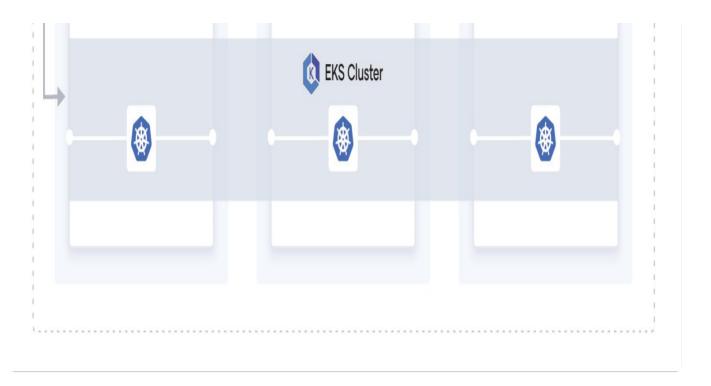

\$ git clone https://github.com/hashicorp/learn-terraform-provision-eks-clust Copy C

Change into the repository directory.

\$ cd learn-terraform-provision-eks-cluster Copy C

This example repository contains configuration to provision a VPC, security groups, and an EKS cluster with the following architecture:

The configuration defines a new VPC in which to provision the cluster, and uses the public EKS module to create the required resources, including Auto Scaling Groups, security groups, and IAM Roles and Policies.

Open the main.tf file to review the module configuration. The eks_managed_node_groups parameter configures the cluster with three nodes across two node groups.

```
main.tf

eks_managed_node_groups = {
  one = {
    name = "node-group-1"

    instance_types = ["t3.small"]

    min_size = 1
    max_size = 3
    desired_size = 2
}

two = {
    name = "node-group-2"
    instance_types = ["t3.small"]
```

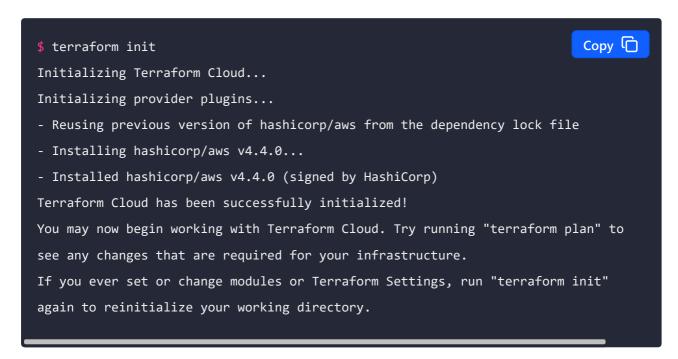

```
min_size = 1
max_size = 2
desired_size = 1
}
}
```

Initialize configuration

Set the TF_CLOUD_ORGANIZATION environment variable to your Terraform Cloud organization name. This will configure your Terraform Cloud integration.

```
$ export TF_CLOUD_ORGANIZATION=
```

Initialize your configuration. Terraform will automatically create the learn-terraform-eks workspace in your Terraform Cloud organization.

⚠ Note

This tutorial assumes that you are using a tutorial-specific Terraform Cloud organization with a global variable set of your AWS credentials. Review the <u>Create a Credential Variable Set</u> for detailed guidance. If you are using a scoped variable set, <u>assign it to your new workspace</u> now.

Provision the EKS cluster

Run terraform apply to create your cluster and other necessary resources. Confirm the operation with a yes.

This process can take up to 10 minutes. Upon completion, Terraform will print your configuration's outputs.

```
Copy [
$ terraform apply
Terraform used the selected providers to generate the following execution plan. Resource
 + create
<= read (data resources)
Terraform will perform the following actions:
Plan: 55 to add, 0 to change, 0 to destroy.
Changes to Outputs:
 + cluster_endpoint = (known after apply)
 + cluster_name
                            = (known after apply)
 + cluster_security_group_id = (known after apply)
 + region
                             = "us-east-2"
Do you want to perform these actions in workspace "learn-terraform-eks"?
 Terraform will perform the actions described above.
 Only 'yes' will be accepted to approve.
 Enter a value: yes
```

```
Apply complete! Resources: 55 added, 0 changed, 0 destroyed.

Outputs:

cluster_endpoint = "https://128CA2A0D737317D36E31D0D3A0C366B.gr7.us-east-2.eks.amazonaws
cluster_name = "education-eks-IKQYD53K"

cluster_security_group_id = "sg-0f836e078948afb70"

region = "us-east-2"
```

Configure kubectl

After provisioning your cluster, you need to configure kubect1 to interact with it.

First, open the outputs.tf file to review the output values. You will use the region and cluster_name outputs to configure kubectl.

```
outputs.tf
output "cluster_endpoint" {
 description = "Endpoint for EKS control plane"
 value = module.eks.cluster_endpoint
output "cluster_security_group_id" {
 description = "Security group ids attached to the cluster control plane"
             = module.eks.cluster_security_group_id
output "region" {
 description = "AWS region"
 value = var.region
output "cluster_name" {
 description = "Kubernetes Cluster Name"
             = module.eks.cluster name
```

Run the following command to retrieve the access credentials for your cluster and configure kubect1.

```
$ aws eks --region $(terraform output -raw region) update-kubeconfig \ Copy C
```

You can now use kubect1 to manage your cluster and deploy Kubernetes configurations to it.

Verify the Cluster

Use kubect1 commands to verify your cluster configuration.

First, get information about the cluster.

```
$ kubectl cluster-info

Kubernetes control plane is running at https://128CA2A0D737317D36E31D0D3A0C366B.gr7.us-eactoreDNS is running at https://128CA2A0D737317D36E31D0D3A0C366B.gr7.us-east-2.eks.amazonav

To further debug and diagnose cluster problems, use 'kubectl cluster-info dump'.
```

Notice that the Kubernetes control plane location matches the cluster_endpoint value from the terraform apply output above.

Now verify that all three worker nodes are part of the cluster.

```
Copy 🗀
$ kubectl get nodes
NAME
                                           STATUS
                                                     ROLES
                                                              AGE
                                                                      VERSION
                                                                      v1.24.7-eks-fb459a0
ip-10-0-1-50.us-east-2.compute.internal
                                           Ready
                                                     <none>
                                                              6m20s
ip-10-0-3-158.us-east-2.compute.internal
                                           Ready
                                                              6m41s
                                                                      v1.24.7-eks-fb459a0
                                                     <none>
ip-10-0-3-46.us-east-2.compute.internal
                                                                      v1.24.7-eks-fb459a0
                                           Ready
                                                              6m14s
                                                     <none>
```

You have verified that you can connect to your cluster using kubect1 and that all three worker nodes are healthy. Your cluster is ready to use.

Clean up your workspace

You have now provisioned an EKS cluster, configured kubect1, and verified that your cluster is ready to use.

To learn how to manage your EKS cluster using the Terraform Kubernetes Provider, leave your cluster running and continue to the <u>Kubernetes provider tutorial</u>.

This tutorial's example configuration contains **only** the configuration to create an EKS cluster. You can also use Terraform to manage the Kubernetes objects deployed to a cluster, such as Deployments and Services. We recommend that you keep the Terraform configuration for each of those concerns separate, since their workflows and owners often differ.

Destroy the resources you created in this tutorial to avoid incurring extra charges. Respond yes to the prompt to confirm the operation.

```
Copy [
$ terraform destroy
Plan: 0 to add, 0 to change, 55 to destroy.
Changes to Outputs:
  - cluster_endpoint = "https://128CA2A0D737317D36E31D0D3A0C366B.gr7.us-east-2.
  - cluster_name
                             = "education-eks-IKQYD53K" -> null
  - cluster_security_group_id = "sg-0f836e078948afb70" -> null
  - region
                             = "us-east-2" -> null
Do you really want to destroy all resources?
  Terraform will destroy all your managed infrastructure, as shown above.
 There is no undo. Only 'yes' will be accepted to confirm.
  Enter a value: yes
Destroy complete! Resources: 55 destroyed.
```

If you used Terraform Cloud for this tutorial, after destroying your resources, delete the learn-terraform-eks workspace from your Terraform Cloud organization.

Next steps

For more information on the EKS module, visit the EKS module page in the Terraform Registry.

To learn how to manage Kubernetes resources, your EKS cluster, or existing Kubernetes clusters, visit the <u>Kubernetes provider tutorial</u>.

You can also use the Kubernetes provider to deploy custom resources.

For a more in-depth Kubernetes example, see <u>Deploy Consul and Vault on a Kubernetes Cluster</u> <u>using Run Triggers</u> (this tutorial is GKE based).

Manage AWS Services

Use the AWS provider to manage AWS services with Terraform. Configure IAM policy documents, deploy serverless functions with Lambda, use application load balancers to schedule near-zero downtime releases, manage RDS and more.
